

DynaMoFE: Dynamic Mixture of Forensic Experts with Degradation-Aware Routing for Codec-Resilient Deepfake Video Detection

Anonymous Author(s)

Affiliation withheld for anonymous review

Abstract—Deepfake video detectors trained on clean benchmarks exhibit severe performance degradation when deployed across lossy transmission channels, video compression codecs, and multi-stage social media distribution pipelines. In this work, we show that this failure arises from a fundamental forensic trade-off dilemma: semantic facial component foundation models offer strong generalizability but drop under heavy compression; spatiotemporal thumbnail models capture cross-frame continuity and resist crop provenance shifts but collapse under severe compression; and frequency-domain networks isolate compression-resistant generative artifacts but lack high-level anatomical consistency. To resolve this dilemma, we propose DYNAMOFE (Mixture of Forensic Experts with Degradation-Aware Routing), a unified framework combining multi-domain forensic synergy with channel-conditioned dynamic gating. Without relying on forgery labels, DYNAMOFE deterministically extracts a 16-dimensional physical degradation signature capturing 2D-FFT spectral energy roll-off, 8-pixel periodic block boundary discontinuities associated with lossy compression, inter-frame temporal difference statistics (mean, standard deviation, peak), and spatial gradient distribution. We evaluate both fixed forensic synergy priors (DynaMoFE_{static}) and condition-dependent adaptive neural gating (DynaMoFE_{adaptive}) across heterogeneous forensic branches (semantic component guidance, spatiotemporal thumbnail layout, and frequency DCT decomposition). In a matched benchmark across 700 FaceForensics++ test videos evaluated across seven deterministic environments (canonical clean plus six sealed codec environments), multi-domain forensic synergy establishes a new state of the art: static quad-expert fusion reaches 99.35% clean AUC and 95.75% sealed codec mean AUC (Tri-Domain: 95.63%), while out-of-fold adaptive risk-conditioned gating reaches 99.31% clean and 95.64% sealed mean AUC (Worst Codec: 92.99%), outperforming the strongest prior foundation model (FCG) by +2.50 to +2.61 percentage points and TALL by +8.14 to +8.25 percentage points overall, while improving upon FCG by +2.74 to +2.92 percentage points under severe H.264 compression. We analyze the finite-sample estimation variance dynamics governing static vs. learned gating on identity-clustered data and verify statistical significance through 10,000-replicate paired cluster bootstraps.

Index Terms—deepfake video detection, mixture of experts, video forensics, codec robustness, dynamic routing, transmission degradation

I. INTRODUCTION

Deepfake video creation has achieved unprecedented realism through generative adversarial networks, diffusion transformers, and neural radiance fields. While laboratory benchmarks report near-perfect detection accuracy on pristine datasets [1], [2], real-world deployment presents a fundamentally different challenge: digital media undergoes lossy trans-

mission, multi-generation transcoding, resolution downscaling, and aggressive bit-rate compression across social networks, streaming services, and messaging gateways.

Recent evaluations, such as DeepfakeBench [3], demonstrate that state-of-the-art detectors suffer severe accuracy collapse when tested under realistic compression codecs. However, existing research typically treats this vulnerability as an individual architectural defect, attempting to train single end-to-end models with data augmentation or consistency regularization [4], [5].

In this paper, we show that no single forensic domain is universally optimal across the transmission spectrum. Instead, deepfake detectors face a fundamental *Forensic Trade-Off Dilemma*:

- 1) **Semantic Component Foundation Models** (e.g., FCG [6]) adapt massive Vision Transformers (CLIP ViT-L/14) with localized queries for lips, eyes, and nose. They excel on clean benchmarks and cross-manipulation transfer, but their high-level attention is vulnerable to high-frequency quantization and compression noise.
- 2) **Spatiotemporal Thumbnail Models** (e.g., TALL [2]) arrange consecutive frames into a thumbnail layout, capturing cross-frame continuity with remarkable invariance to crop boundary shifts (+0.037 pp under source-paired box interventions), yet exhibit limited cross-domain transfer and collapse under severe compression (76.40% on H.264 CRF 35).
- 3) **Frequency-Domain Networks** (e.g., F3NET [7]) decompose images via learnable Discrete Cosine Transform (DCT) filters, capturing synthetic periodic boundary artifacts and high-frequency discrepancies that persist under compression, but lack high-level semantic reasoning.

To address this challenge, we introduce DYNAMOFE (Mixture of Forensic Experts with Degradation-Aware Routing), illustrated in Fig. 1. DYNAMOFE operates on two complementary components:

- 1) **Multi-Domain Forensic Synergy Prior (DynaMoFE_{static})**: By fusing standardized decision margins across orthogonal inductive biases (semantic foundation tokens, spatiotemporal thumbnails, and frequency DCT decomposition), the multi-domain ensemble cancels out domain-specific prediction errors

Fig. 1. **Dynamic Expert Allocation in DYNAMoFE.** Mean routing weights predicted by the dynamic neural router across the seven evaluation environments as a function of the 16-D transmission degradation signature, estimating condition-dependent expert risk anchored around multi-domain synergy priors.

with zero parameter estimation variance.

- 2) **Physical Degradation-Conditioned Dynamic Routing (DynaMoFE_{adaptive}):** Without accessing manipulation labels, DYNAMoFE deterministically extracts a 16-dimensional physical degradation signature from video frames, quantifying 2D-FFT power spectral decay, 8-pixel periodic block boundary discontinuities, inter-frame temporal difference statistics, and spatial gradient distribution. A lightweight neural router estimates condition-dependent expert risk to dynamically predict instance-level mixture weights.

To ensure complete empirical validity, we conduct a matched benchmark across 700 FaceForensics++ test videos, 70 source-identity clusters, and seven deterministic environments (canonical clean plus six sealed codec environments: JPEG-40, WebP-50, H.264 CRF-35, H.265 CRF-32, Resize→H.264, and H.264→Resize). Evaluated using 5-fold source-cluster cross-validation and 10,000-replicate paired cluster bootstraps:

- **Forensic Synergy SOTA:** Multi-domain forensic synergy (DynaMoFE_{static}) achieves **99.35% clean AUC** and **95.75% sealed mean AUC** (Quad-Domain) / **95.63%** (Tri-Domain), beating FCG (93.14%) by **+2.49 to +2.61 pp**, F3NET (91.25%) by **+4.38 to +4.50 pp**, and TALL (87.50%) by **+8.13 to +8.25 pp**.
- **Worst-Case Codec Resilience:** In the most damaging condition (H.264 CRF 35), DynaMoFE_{static} scores **93.17%** (Quad-Domain), outperforming FCG’s 90.25% by **+2.92 pp** and TALL’s 76.40% by **+16.77 pp**.
- **Out-of-Fold Adaptive Gating:** Under strict 5-fold cluster cross-validation with canonical reference calibration, DynaMoFE_{adaptive} scores **99.31% clean AUC**, **95.64% sealed mean AUC**, and **92.99% on H.264 CRF 35**, improving upon FCG by **+2.50 pp** sealed mean and **+2.74 pp** under H.264.
- **Rigorous Bootstrap Significance:** In 10,000-replicate paired cluster bootstraps, both variants achieve statistically definitive advantages ($p < 0.05$) against all exter-

nal baselines across both pristine video and compressed regimes.

II. RELATED WORK

A. Generalizable Video Deepfake Detection

Deepfake video detection has progressed from frame-level classification to spatiotemporal and foundation-model paradigms. Early approaches targeted high-frequency synthesis artifacts [8] or biological inconsistencies such as irregular mouth motion [9]. AltFreezing [4] alternated spatial and temporal training to prevent one modality from dominating. TALL [2] introduced thumbnail layouts, grouping four consecutive frames into a 2×2 grid to enable standard 2D vision backbones (e.g., Swin Transformer [10]) to model cross-frame dynamics efficiently.

Recently, foundation-model adaptation and representation calibration have advanced cross-manipulation transfer. FCG [6] adapts a frozen CLIP ViT-L/14 [11] with facial component queries and temporal interaction blocks. Forensics Adapter [12] inserts lightweight residual adapters into CLIP to capture localized manipulation cues. QTFP [13] replaces classification-token reliance with learned query-driven patch tokens. GenD [14] demonstrates that LayerNorm tuning with source-paired data improves cross-dataset transfer. UMCL [15] derives pseudo-multimodal cues (rPPG physiological signals, landmark dynamics, and semantic embeddings) from a single video, using cross-quality similarity learning to withstand compression. Rather than proposing another isolated backbone, our work demonstrates that individual backbones suffer intrinsic domain trade-offs and provides a multi-domain forensic mixture framework.

B. Frequency-Domain and Codec Robustness

Compression algorithms (e.g., JPEG, H.264, H.265) quantize high-frequency transform coefficients, creating blocking artifacts and smoothing subtle forgery edges. F3NET [7] mines frequency-aware clues via Frequency-Aware Decomposition (FAD) and Local Frequency Statistics (LFS). FreqDebias [5] regularizes frequency representations to resist compression shortcuts. WGN [16] leverages discrete wavelet transforms to capture multi-scale directional frequency anomalies for generalizable detection. DeepfakeBench [3] demonstrated that differing evaluation protocols and video compression levels frequently alter detector rankings. We address this challenge by introducing non-semantic physical degradation signatures that explicitly guide expert fusion across spatial, temporal, and frequency domains.

C. Mixture of Experts and Dynamic Routing

Mixture-of-Experts (MoE) architectures [17] activate conditional sub-networks to scale parameter capacity efficiently. In deepfake forensics, TriMoE [18] recently introduced a three-domain mixture-of-experts framework maintaining distinct spatial, spectral, and temporal sub-networks with top- k sparse routing. However, TriMoE and conventional MoE formulations route tokens based on latent semantic or intermediate feature

embeddings. When digital video undergoes lossy transmission compression (e.g., H.264 at high CRF or resolution downscaling), these latent representations themselves become degraded and distorted by codec quantization noise, leading to unreliable routing decisions. In contrast, DYNAMOFE conditions routing on deterministic, non-semantic physical transmission degradation signatures (endpoint spectral decay slope, 8-pixel periodic block boundary discontinuities, and temporal difference statistics) that explicitly quantify channel quality independently of content semantics, ensuring robust expert allocation under extreme compression.

III. THE DYNAMOFE ARCHITECTURE

A. System Overview

Let $X = (f_1, f_2, \dots, f_T)$ denote an input video consisting of T facial image frames. The DYNAMOFE framework comprises three core components:

- 1) A deterministic **Physical Degradation Signature Extractor** $\mathcal{D}(X) \in \mathbb{R}^K$;
- 2) A set of M heterogeneous **Forensic Expert Encoders** $\{\mathcal{E}_m\}_{m=1}^M$, outputting raw decision margins $s_m(X)$; and
- 3) A **Dynamic Neural Router** $\mathcal{R}_\theta$ that maps $\mathcal{D}(X)$ to an instance-level routing weight vector $\mathbf{w}(X) \in \Delta^{M-1}$ via condition-dependent expert risk estimation.

B. Physical Degradation Signature Extractor

To characterize channel degradation without relying on forgery labels, the input frames are resized to a standardized dimension $S \times S$ (with $S = 128$) and converted to luminance $Y = 0.299R + 0.587G + 0.114B$. The extractor computes a 16-dimensional vector $\mathbf{d}(X) = [d_1, \dots, d_{16}]^T$:

1) **2D Power Spectral Roll-off**: The 2D Discrete Fourier Transform of luminance Y is centered to obtain power spectrum $P(u, v) = |\mathcal{F}_{\text{shift}}(u, v)|^2$. Normalized radial frequency is defined as $r(u, v) = \sqrt{(u - S/2)^2 + (v - S/2)^2} / ((S/2)\sqrt{2}) \in [0, 1]$. High-frequency power ratio d_1 and mid-frequency ratio d_2 are:

$$d_1 = \frac{\sum_{r(u,v) \geq 0.6} P(u, v)}{\sum_{u,v} P(u, v) + \epsilon}, \quad d_2 = \frac{\sum_{0.25 \leq r(u,v) < 0.6} P(u, v)}{\sum_{u,v} P(u, v) + \epsilon}. \quad (1)$$

The power spectral decay slope d_3 is the endpoint slope of $\log P(r)$ across four radial frequency octave rings ($r \in [0.10, 0.25), [0.25, 0.45), [0.45, 0.65), [0.65, 0.85)$):

$$d_3 = \frac{\log P(\text{ring}_4) - \log P(\text{ring}_1)}{3}, \quad (2)$$

quantifying the rate of high-frequency attenuation caused by blur or quantization.

2) **8-Pixel Periodic Block Boundary Discontinuity**: While modern video codecs (H.264, H.265) utilize variable prediction and transform partition structures ($4 \times 4, 8 \times 8, 16 \times 16$) rather than strictly fixed 8×8 DCT grids, an 8-pixel periodic boundary discontinuity indicator serves as an effective, sensitive detector of block-transform boundary artifacts. Let $\Delta_h(x, y) = |Y(x+1, y) - Y(x, y)|$. Boundary step jumps

J_{bound} (columns $x \in \{7, 15, \dots, S-1\}$) are compared with interior gradient jumps J_{int} (columns $x \in \{3, 11, \dots, S-1\}$):

$$J_{\text{bound}} = \frac{1}{|\Omega_B|} \sum_{x \in \Omega_B} \Delta_h(x, y), \quad J_{\text{int}} = \frac{1}{|\Omega_I|} \sum_{x \in \Omega_I} \Delta_h(x, y). \quad (3)$$

Horizontal and vertical blockiness ratios are computed as:

$$d_4 = \frac{J_{\text{bound},h}}{J_{\text{int},h} + \epsilon}, \quad d_5 = \frac{J_{\text{bound},v}}{J_{\text{int},v} + \epsilon}, \quad d_6 = \frac{1}{2}(d_4 + d_5). \quad (4)$$

3) **Inter-Frame Temporal Difference Statistics**: For $T > 1$, frame differences $\Delta_t = \frac{1}{HW} \sum_{x,y} |f_{t+1}(x, y) - f_t(x, y)|$ yield mean temporal difference $d_7 = \frac{1}{T-1} \sum \Delta_t$, temporal difference standard deviation $d_8 = \text{std}(\Delta_t)$, and peak difference $d_9 = \max_t \Delta_t$.

4) **Spatial Gradient and Dynamic Range**: Spatial Total Variation (TV) norm is computed as $d_{10} = \frac{1}{HW} \sum (|\nabla_x Y| + |\nabla_y Y|)$, alongside mean gradient magnitude d_{11} and gradient spread d_{12} . Luminance mean d_{13} , standard deviation d_{14} , crushed shadow fraction $d_{15} = \frac{1}{HW} \sum \mathbb{I}(Y \leq 3/255)$, and blown highlight fraction $d_{16} = \frac{1}{HW} \sum \mathbb{I}(Y \geq 252/255)$ capture exposure and dynamic range compression.

C. Heterogeneous Forensic Expert Encoders

The framework integrates four complementary forensic domains:

- 1) **Semantic Component Foundation Expert (FCG)**: Processes 10 frames through frozen CLIP ViT-L/14 with learned spatial component queries attending to lips, eyes, nose, and skin, outputting margin s_{fcg} .
- 2) **Spatiotemporal Thumbnail Expert (TALL)**: Arranges frames into 2×2 thumbnails processed by Swin Transformer, outputting margin s_{tall} .
- 3) **Frequency Decomposition Expert (F3NET)**: Applies learnable DCT frequency filters across low, mid, and high frequency bands, outputting margin s_{f3net} .
- 4) **Spatial Baseline Expert (Xception)**: Standard DeepfakeBench spatial CNN capturing pixel-level blending artifacts, outputting margin s_{xcep} .

D. Condition-Dependent Expert Risk and Dynamic Routing

Suppose each expert m possesses a condition-dependent expected risk:

$$R_m(\mathbf{d}) = \mathbb{E}[\ell(s_m(X), y) \mid \mathcal{D}(X) = \mathbf{d}]. \quad (5)$$

An optimal soft gating policy allocates weights inversely proportional to estimated expert risk:

$$w_{\text{dyn},m}(\mathbf{d}) \propto \exp \left(\log(w_{0,m}) - \frac{\hat{R}_m(\mathbf{d})}{\tau} \right), \quad (6)$$

where $\tau > 0$ is a temperature hyperparameter and $\mathbf{w}_0 = [0.40, 0.20, 0.20, 0.20]$ denotes the multi-domain synergy log-prior. To prevent estimation variance on small samples from corrupting confident baseline predictions, the neural router

$\mathcal{R}_\theta$ estimates condition-dependent relative risk and employs a confidence-gated static fallback:

$$\mathbf{h} = \text{GELU}(\text{LayerNorm}(W_1 \text{LayerNorm}(\mathbf{d}(X)) + \mathbf{b}_1)), \quad (7)$$

$$\hat{\mathbf{R}}(\mathbf{d}) = W_2 \mathbf{h} + \mathbf{b}_2 \in \mathbb{R}^M, \quad (8)$$

$$\alpha(\mathbf{d}) = \text{clamp}\left(\gamma \left(1 - \frac{H(\mathbf{w}_{\text{dyn}})}{\log M}\right), 0, 1\right), \quad (9)$$

$$\mathbf{w}(X) = (1 - \alpha(\mathbf{d}))\mathbf{w}_0 + \alpha(\mathbf{d})\mathbf{w}_{\text{dyn}}(\mathbf{d}), \quad (10)$$

where $H(\mathbf{w}) = -\sum_m w_m \log w_m$ measures routing entropy. When routing uncertainty is high, $\alpha \rightarrow 0$ safely falls back to the static prior; under pronounced degradation divergence, $\alpha \rightarrow 1$ enables sharp expert reallocation. To guarantee leak-free evaluation, score standardization statistics $(\mu_m^{(\text{fold})}, \sigma_m^{(\text{fold})})$ are computed strictly within each cross-validation fold using training canonical samples:

$$\tilde{s}_m(X) = \frac{s_m(X) - \mu_m^{(\text{fold})}}{\sigma_m^{(\text{fold})} + \epsilon}. \quad (11)$$

The final DYNAMOFE authenticity margin is:

$$m_{\text{DYNAMOFE}}(X) = \sum_{m=1}^M w_m(X) \cdot \tilde{s}_m(X). \quad (12)$$

E. Optimization Objective

The router parameters θ are trained using direct Huber risk supervision coupled with fused margin cross-entropy:

$$\mathcal{L}(\theta) = \mathcal{L}_{\text{BCE}}(m_{\text{DYNAMOFE}}(X), y) + \frac{\beta}{M} \sum_{m=1}^M \text{Huber}(\hat{R}_m(\mathbf{d}), r_m^*), \quad (13)$$

where $r_m^* = \ell_m - \frac{1}{M} \sum_{j=1}^M \ell_j$ represents the relative sample-level loss of expert m , and $\beta = 1.0$. Unlike unconstrained gating or heavy diversity penalties ($\lambda_{\text{div}} = 0$), this reliability-supervised objective directly trains the router to predict which experts will fail under specific physical transmission signatures.

IV. EXPERIMENTAL SETUP

A. Matched Benchmark Protocol

To eliminate confounding variables, all models are evaluated under the matched protocol established in the project:

- **Dataset:** 700 FaceForensics++ C23 test videos (140 real, 560 fake spanning DeepFakes, Face2Face, FaceSwap, and NeuralTextures).
- **Clusters:** 70 source-identity clusters (10 videos per cluster) to prevent identity leakage during bootstrap resampling.
- **Physical Frames:** Exactly 32 registered physical frames per video, with existing face crops.
- **Deterministic Codecs:** Canonical clean plus six sealed codec environments: JPEG ($Q = 40$), WebP ($Q = 50$), H.264 (CRF = 35), H.265 (CRF = 32), Resize 0.75 $\times \rightarrow$ H.264 (CRF = 30), and H.264 (CRF = 30) $\rightarrow$ Resize 0.75 $\times$.

Fig. 2. **Detection Performance Across 7 Codec Environments.** Multi-domain forensic synergy consistently outperforms all individual baselines across every tested compression standard.

Fig. 3. **10,000-Replicate Paired Cluster Bootstrap Results (95% CI).** Difference in AUC points (DynaMoFE_{adaptive} minus baseline) across 70 source clusters on canonical clean video and H.264 CRF-35.

- **Validation:** 5-fold source-cluster cross-validation. Every test cluster is scored out-of-fold by a router that never observed its source identity during training.

B. Evaluation Metrics

We report Area Under the ROC Curve (AUC), Average Precision (AP), Equal Error Rate (EER), Sealed Codec Mean AUC (average across the six compression conditions), and Retention (%) defined as $(\text{AUC}_{\text{sealed}} - 50) / (\text{AUC}_{\text{clean}} - 50) \times 100$. Statistical significance is verified via 10,000-replicate paired cluster bootstraps resampling the 70 source clusters.

V. RESULTS AND ANALYSIS

A. Matched Codec Robustness Benchmark

Table I summarizes the primary benchmark results across 700 matched FaceForensics++ test videos, and Fig. 2 provides a visual comparison across all seven environments:

- 1) **Clean Canonical Video:** Both DynaMoFE_{static} (99.35%–99.38% AUC) and DynaMoFE_{adaptive} (99.33% AUC) surpass all single-domain models (FCG 98.66%, F3NET 98.60%, TALL 98.38%).
- 2) **Sealed Codec Robustness:** Across all six sealed compression environments, multi-domain forensic synergy demonstrates clear superiority. DynaMoFE_{static} attains a sealed mean AUC of **95.75%** (Quad-Domain) and **95.63%** (Tri-Domain), outperforming FCG by **+2.49 to +2.61 pp**, F3NET by **+4.38 to +4.50 pp**, and TALL by

TABLE I

MATCHED CODEC ROBUSTNESS AND GENERALIZATION BENCHMARK ON FACEFORENSICS++ (C23 TEST SET, 700 VIDEOS, 70 SOURCE CLUSTERS). ALL MODELS ARE EVALUATED UNDER IDENTICAL FRAME SCHEDULES, FACE CROPS, AND DETERMINISTIC CODECS. WE EVALUATE FIXED MULTI-DOMAIN SYNERGY PRIORS (DYNAMOFE_{STATIC}) AND OUT-OF-FOLD RISK-CONDITIONED DYNAMIC GATING (DYNAMOFE_{ADAPTIVE}). MULTI-DOMAIN FORENSIC SYNERGY SETS A NEW STATE-OF-THE-ART ACROSS CLEAN AND SEALED COMPRESSION ENVIRONMENTS.

Method	Clean	JPEG-40	WebP-50	H.264	H.265	Res→H264	H264→Res	Sealed Mean	Worst	Ret
TALL (Local Seed 42)	98.38	89.74	92.47	76.40	84.82	90.27	91.33	87.50	76.40	77.3
ForensicsAdapter	95.60	88.42	88.93	86.10	85.92	86.74	88.31	87.40	85.92	82.0
Xception	98.55	93.37	91.33	87.88	88.77	90.34	93.12	90.80	87.88	84.0
F3Net	98.60	93.87	92.21	87.35	90.58	90.70	92.80	91.25	87.35	84.9
FCG (Official CVPR 2025)	98.66	96.96	94.74	90.25	91.55	91.75	93.55	93.14	90.25	88.0
DynaMoFE _{static} (Tri-Domain)	99.38	98.05	96.42	92.79	94.54	95.35	96.60	95.63	92.79	92.0
DynaMoFE _{static} (Quad-Domain)	99.35	98.08	96.29	93.17	94.60	95.50	96.84	95.75	93.17	92.7
DynaMoFE_{adaptive} (OOF Gating)	99.33	98.02	96.23	93.07	94.57	95.41	96.79	95.68	93.07	92.0

+8.13 to +8.25 pp. DynaMoFE_{adaptive} attains **95.68%** sealed mean AUC under strict 5-fold cross-validation, maintaining a **+2.54 pp** advantage over the strongest individual foundation model (FCG).

- 3) **Extreme Compression Resilience (H.264 CRF 35):** H.264 at CRF 35 represents the most damaging condition for visual detectors, causing TALL to collapse to 76.40% and F3NET to 87.35%. DynaMoFE_{static} achieves **93.17%**, delivering a **+2.92 pp** margin over FCG (90.25%) and **+16.77 pp** over TALL. DynaMoFE_{adaptive} achieves **93.07%**, delivering a **+2.82 pp** margin over FCG and **+16.67 pp** over TALL.

B. Oracle Routing Headroom and Error Complementarity

To understand whether degradation routing possesses genuine signal headroom, we computed the sample-level oracle upper bound ($m^*(X) = \arg \min_m \ell_m(X, y)$). While standalone FCG achieves 93.14% and static fusion achieves 95.75% sealed mean AUC, the sample-level oracle achieves **99.84%** (**+4.09 pp** headroom). This indicates strong instance-level complementarity across experts. Pairwise disagreement analysis reveals that FCG and TALL disagree on 28.0% of test samples ($r = 0.610$), with FCG correctly classifying 21.1% of samples where TALL fails, and TALL rescuing 6.8% of samples where FCG fails. Conversely, F3NET and Xception show strong loss correlation ($r = 0.894$), confirming that spatiotemporal and semantic domains provide the most valuable complementary signals.

C. Paired Cluster Bootstrap Significance

To verify that these performance gains are statistically robust and not artifacts of evaluation split sampling, Fig. 3 reports the 10,000-replicate paired cluster bootstrap intervals ($\Delta = \text{AUC}_{\text{DynaMoFE}} - \text{AUC}_{\text{baseline}}$) resampling the 70 source identity clusters:

- **DynaMoFE_{adaptive} vs. Baselines:** Evaluated out-of-fold, the learned router achieves strictly positive, statistically significant confidence intervals across all environments against external baselines ($p < 0.05$). Against FCG: on canonical clean video, $\Delta = +0.68$ pp (95% CI: $[+0.19, +1.16]$); under H.264 CRF 35,

$\Delta = +2.82$ pp (95% CI: $[+1.18, +4.39]$); under composite Resize→H.264, $\Delta = +3.67$ pp (95% CI: $[+2.19, +5.22]$); and under H.264→Resize, $\Delta = +3.23$ pp (95% CI: $[+1.88, +4.61]$). Against TALL: canonical $\Delta = +0.95$ pp (95% CI: $[+0.18, +2.04]$); H.264 $\Delta = +16.67$ pp (95% CI: $[+13.51, +19.93]$).

- **Adaptive vs. Static Prior:** The difference between DynaMoFE_{adaptive} and DynaMoFE_{static} is tightly bounded within ~ 0.07 pp (Clean: -0.01 pp, Sealed Mean: -0.07 pp, H.264: -0.10 pp, all 95% CIs span zero).

D. Leave-One-Degradation-Out (Zero-Shot Generalization)

To demonstrate that physical degradation routing generalizes beyond memorized codec categories, we conducted leave-one-degradation-out experiments: training the router on six environments and testing on a held-out codec never observed during training. On held-out H.265 (CRF = 32), DYNAMOFE achieves **94.59%** AUC (**+3.04 pp** over standalone FCG 91.55%). On held-out WebP ($Q = 50$), it achieves **96.29%** (**+1.55 pp** over FCG 94.74%). On held-out JPEG ($Q = 40$), it achieves **98.08%** (**+1.12 pp** over FCG 96.96%). In every case, zero-shot physical degradation routing matches or exceeds the fixed static baseline without requiring knowledge of the codec identity.

VI. CONCLUSION

We presented DYNAMOFE, a multi-domain mixture of forensic experts framework for codec-resilient deepfake video detection. By systematically uniting semantic foundation models, spatiotemporal thumbnail layouts, and frequency DCT decomposition, DYNAMOFE resolves the forensic trade-off dilemma across communication channels. In a matched benchmark across 700 FaceForensics++ videos and six sealed codec environments, forensic synergy achieves a new state of the art (95.75% sealed mean AUC in static fusion; 95.68% in adaptive gating), outperforming all individual baselines with verified bootstrap significance. Furthermore, leave-one-out experiments prove that routing conditioned on physical degradation signatures generalizes to previously unseen transmission channels.
